

Protocol for the Examination of Specimens From Patients With Invasive Carcinoma of the Breast

Protocol applies to all invasive carcinomas of the breast, including microinvasive carcinoma with or without ductal carcinoma in situ (DCIS)

Based on AJCC/UICC TNM, 7th edition
Protocol web posting date: January 2016

Procedures

- Complete Excision (Less Than Total Mastectomy, Including Specimens Designated Biopsy, Lumpectomy, Quadrantectomy, and Partial Mastectomy) With or Without Axillary Contents
- Mastectomy (Total, With or Without Axillary Contents; Modified Radical; Radical)

The College does not permit reproduction of any substantial portion of these protocols without its written authorization. The College hereby authorizes use of these protocols by physicians and other health care providers in reporting on surgical specimens, in teaching, and in carrying out medical research for nonprofit purposes. This authorization does not extend to reproduction or other use of any substantial portion of these protocols for commercial purposes without the written consent of the College.

The CAP also authorizes physicians and other health care practitioners to make modified versions of the Protocols solely for their individual use in reporting on surgical specimens for individual patients, teaching, and carrying out medical research for non-profit purposes.

The CAP further authorizes the following uses by physicians and other health care practitioners, in reporting on surgical specimens for individual patients, in teaching, and in carrying out medical research for non-profit purposes: (1) **Dictation** from the original or modified protocols for the purposes of creating a text-based patient record on paper, or in a word processing document; (2) **Copying** from the original or modified protocols into a text-based patient record on paper, or in a word processing document; (3) The use of a **computerized system** for items (1) and (2), provided that the Protocol data is stored intact as a single text-based document, and is not stored as multiple discrete data fields.

Other than uses (1), (2), and (3) above, the CAP does not authorize any use of the Protocols in electronic medical records systems, pathology informatics systems, cancer registry computer systems, computerized databases, mappings between coding works, or any computerized system without a written license from the CAP.

Any public dissemination of the original or modified Protocols is prohibited without a written license from the CAP.

The College of American Pathologists offers these protocols to assist pathologists in providing clinically useful and relevant information when reporting results of surgical specimen examinations of surgical specimens. The College regards the reporting elements in the “Surgical Pathology Cancer Case Summary” portion of the protocols as essential elements of the pathology report. However, the manner in which these elements are reported is at the discretion of each specific pathologist, taking into account clinician preferences, institutional policies, and individual practice.

The College developed these protocols as an educational tool to assist pathologists in the useful reporting of relevant information. It did not issue the protocols for use in litigation, reimbursement, or other contexts. Nevertheless, the College recognizes that the protocols might be used by hospitals, attorneys, payers, and others. Indeed, effective January 1, 2004, the Commission on Cancer of the American College of Surgeons mandated the use of the required data elements of the protocols as part of its Cancer Program Standards for Approved Cancer Programs. Therefore, it becomes even more important for pathologists to familiarize themselves with these documents. At the same time, the College cautions that use of the protocols other than for their intended educational purpose may involve additional considerations that are beyond the scope of this document.

The inclusion of a product name or service in a CAP publication should not be construed as an endorsement of such product or service, nor is failure to include the name of a product or service to be construed as disapproval.

CAP Invasive Breast Carcinoma Protocol Revision History

Version Code

The definition of the version code can be found at www.cap.org/cancerprotocols.

Version: InvasiveBreast 3.3.0.0

Summary of Changes

The following changes have been made since the December 2013 release.

The following data elements were modified:

- Procedure
- Histologic Type
- Tumor Focality
- Margins
- Lymph Nodes
- Lymph-Vascular Invasion
- Distant Metastasis (changed to required only if confirmed pathologically)
- Microcalcifications

Surgical Pathology Cancer Case Summary

Protocol web posting date: January 2016

INVASIVE CARCINOMA OF THE BREAST: Complete Excision (Less Than Total Mastectomy, Including Specimens Designated Biopsy, Lumpectomy, Quadrantectomy, and Partial Mastectomy With or Without Axillary Contents) and Mastectomy (Total, With or Without Axillary Contents; Modified Radical; Radical)

Select a single response unless otherwise indicated.

Specimen Identification

The following 4 elements identifying the specimen may be listed separately or on 1 line:

Procedure (Note A)

- Excision without image-guided localization
- Excision with image-guided localization
- Total mastectomy (including nipple and skin)
- Other (specify): _____
- Not specified

Lymph Node Sampling (select all that apply) (required only if lymph nodes are present in the specimen) (Note B)

- Sentinel lymph node(s)
- Axillary dissection (partial or complete dissection)
- Lymph nodes present within the breast specimen (ie, intramammary lymph nodes)
- Other lymph nodes (eg, supraclavicular or location not identified)
Specify location, if provided: _____

Specimen Laterality

- Right
- Left
- Not specified

+ Tumor Site: Invasive Carcinoma (select all that apply) (Note C)

- + Upper outer quadrant
- + Lower outer quadrant
- + Upper inner quadrant
- + Lower inner quadrant
- + Central
- + Nipple
- + Position: ___ o'clock
- + Other (specify): _____
- + Not specified

Tumor Size: Size of Largest Invasive Carcinoma (Note D)

- Microinvasion only (≤ 1 mm)
- Greatest dimension of largest focus of invasion >1 mm: ___ mm
+ Additional dimensions: ___ x ___ mm
- No residual invasive carcinoma after presurgical (neoadjuvant) therapy
- Cannot be determined (explain): _____

Note: The size of the invasive carcinoma should take into consideration the gross findings correlated with the microscopic examination. In some cases, it may be helpful to use information about tumor size from imaging studies. If multiple foci of invasion are present, the size listed is the size of the largest contiguous area of invasion. The size of multiple invasive carcinomas should not be added together. The size does not include adjacent ductal carcinoma in situ (DCIS).

+ Data elements preceded by this symbol are not required. However, these elements may be clinically important but are not yet validated or regularly used in patient management.

If there has been a prior core needle biopsy or incisional biopsy showing a larger area of invasion than in the excisional specimen, the largest dimension of the invasive carcinoma in the prior specimen should be used for T classification, if known.

If there has been prior neoadjuvant treatment and no invasive carcinoma is present, the cancer is classified as yTis if there is residual DCIS and yPT0 if there is no remaining carcinoma. A protocol is not required if no cancer is present in the specimen

Histologic Type (Note E)

- Invasive mammary carcinoma of no special type (ductal, not otherwise specified)
- Micro-invasive mammary carcinoma
- Invasive mammary carcinoma with extensive intraductal component
- Invasive mammary carcinoma with matrix production

- Invasive lobular carcinoma
- Invasive mammary carcinoma, no special type, with lobular features
- Invasive lobular carcinoma with pleomorphic features
- Invasive lobular carcinoma, alveolar variant
- Invasive carcinoma with ductal and lobular features (“mixed type carcinoma”)

- Mucinous carcinoma
- Invasive mammary carcinoma with mucinous features

- Tubular carcinoma
- Invasive mammary carcinoma with tubular features
- Invasive mammary carcinoma, tubulo-lobular variant
- Invasive cribriform carcinoma
- Invasive mammary carcinoma with cribriform features

- Invasive micropapillary carcinoma
- Invasive carcinoma with micropapillary features
- Invasive mammary carcinoma associated with encysted papillary carcinoma
- Invasive papillary carcinoma
- Invasive solid papillary carcinoma
- Encapsulated papillary carcinoma

- Medullary carcinoma
- Invasive mammary carcinoma with medullary features

- Metaplastic carcinoma
- Metaplastic carcinoma with squamous features
- Low grade adenosquamous carcinoma
- Metaplastic carcinoma with low-grade adenosquamous features
- Low-grade fibromatosis-like metaplastic carcinoma
- Metaplastic carcinoma, spindle cell type
- Metaplastic carcinoma, mixed epithelial and mesenchymal type
- Invasive carcinoma with metaplastic features
- Carcinosarcoma

- Adenoid cystic carcinoma
- Invasive mammary carcinoma with apocrine features
- Invasive carcinoma with clear cell (glycogen rich) features
- Invasive mammary carcinoma with neuroendocrine features
- Invasive carcinoma, with signet-ring cell features
- Secretory carcinoma
- Invasive carcinoma, type cannot be determined
- No residual invasive carcinoma after presurgical (neoadjuvant) therapy
- Other(s) (specify): _____

+ Data elements preceded by this symbol are not required. However, these elements may be clinically important but are not yet validated or regularly used in patient management.

Note: The histologic type corresponds to the largest carcinoma. If there are smaller carcinomas of a different type, this information should be included under "Additional Pathologic Findings."

Inflammatory carcinoma requires the presence of clinical findings of erythema and edema involving at least one-third or more of the skin of the breast (see explanation under "Pathologic Staging").

Special type carcinomas should consist of at least 90% pure pattern.

Histologic Grade (Nottingham Histologic Score) (Note F)

Glandular (Acinar)/Tubular Differentiation

- Score 1 (>75% of tumor area forming glandular/tubular structures)
- Score 2 (10% to 75% of tumor area forming glandular/tubular structures)
- Score 3 (<10% of tumor area forming glandular/tubular structures)
- Only microinvasion present (not graded)
- No residual invasive carcinoma after presurgical (neoadjuvant) therapy
- Score cannot be determined

Nuclear Pleomorphism

- Score 1 (nuclei small with little increase in size in comparison with normal breast epithelial cells, regular outlines, uniform nuclear chromatin, little variation in size)
- Score 2 (cells larger than normal with open vesicular nuclei, visible nucleoli, and moderate variability in both size and shape)
- Score 3 (vesicular nuclei, often with prominent nucleoli, exhibiting marked variation in size and shape, occasionally with very large and bizarre forms)
- Only microinvasion present (not graded)
- No residual invasive carcinoma after presurgical (neoadjuvant) therapy
- Score cannot be determined

Mitotic Rate

- Score 1 (≤ 3 mitoses per mm^2) (see Table 1)
- Score 2 (4-7 mitoses per mm^2) (see Table 1)
- Score 3 (≥ 8 mitoses per mm^2) (see Table 1)
- Only microinvasion present (not graded)
- No residual invasive carcinoma after presurgical (neoadjuvant) therapy
- Score cannot be determined
- + Number of mitoses per 10 high-power fields: ____
- + Diameter of microscope field: ____ mm

Overall Grade

- Grade 1 (scores of 3, 4, or 5)
- Grade 2 (scores of 6 or 7)
- Grade 3 (scores of 8 or 9)
- Only microinvasion present (not graded)
- No residual invasive carcinoma after presurgical (neoadjuvant) therapy
- Score cannot be determined

Note: The grade corresponds to the largest area of invasion. If there are smaller foci of invasion of a different grade, this information should be included under "Additional Pathologic Findings."

Tumor Focality (required only if more than 1 focus of invasive carcinoma is present) (Note G)

- Single focus of invasive carcinoma
- Multiple foci of invasive carcinoma
 - + Number of foci: ____
 - + Sizes of individual foci: ____
- No residual invasive carcinoma after presurgical (neoadjuvant) therapy
- Cannot be determined

Note: If there are multiple invasive carcinomas, size, grade, histologic type, and the results of studies for estrogen receptor (ER), progesterone receptor (PgR), and HER2 should pertain to the largest invasive carcinoma. If smaller invasive carcinomas differ in any of these features, this information may be included in the "Comments" section.

Ductal Carcinoma In Situ (DCIS) (select all that apply) (Note H)

- No DCIS is present
- DCIS is present
 - + Negative for extensive intraductal component (EIC)
 - + Positive for EIC
 - + Only DCIS is present after presurgical (neoadjuvant) therapy

+ Size (Extent) of DCIS

- + Estimated size (extent) of DCIS (greatest dimension using gross and microscopic evaluation):
at least ___ mm
- + Additional dimensions: ___ x ___ mm
- + Number of blocks with DCIS: ___
- + Number of blocks examined: ___

Note: The size (extent) of DCIS is an estimation of the volume of breast tissue occupied by DCIS. This information may be helpful for cases with a predominant component of DCIS (eg, DCIS with microinvasion) but may not be necessary for cases of EIC-negative invasive carcinomas.

+ Architectural Patterns (select all that apply)

- + Comedo
- + Paget disease (DCIS involving nipple skin)
- + Cribriform
- + Micropapillary
- + Papillary
- + Solid
- + Other (specify): _____

+ Nuclear Grade (see Table 2)

- + Grade I (low)
- + Grade II (intermediate)
- + Grade III (high)

+ Necrosis

- + Not identified
- + Present, focal (small foci or single cell necrosis)
- + Present, central (expansive "comedo" necrosis)

+ Lobular Carcinoma In Situ (LCIS)

- + Not identified
- + Present

Macroscopic and Microscopic Extent of Tumor (required only if the structures are present and involved) (select all that apply) (Note I)

Skin

- Invasive carcinoma directly invades into the dermis or epidermis without skin ulceration (this does not change the T stage)
- Invasive carcinoma directly invades into the dermis or epidermis with skin ulceration (classified as T4b)
- Satellite skin foci of invasive carcinoma are present (ie, not contiguous with the invasive carcinoma in the breast) (classified as T4b)

Note: Satellite skin foci are typically due to dermal lymph-vascular invasion. The original definition referred to macroscopically clinically evident foci. The clinical significance of satellite skin foci only identified microscopically has not been studied.

Nipple

___ DCIS involves nipple epidermis (Paget disease of the nipple)

Note: This finding does not change the T classification of invasive carcinomas.

Skeletal Muscle

___ Carcinoma invades skeletal muscle

___ Carcinoma invades into skeletal muscle and into the chest wall (classified as T4a)

Note: Invasion into pectoralis muscle is not considered chest wall invasion, and cancers are not classified as T4a unless there is invasion deeper than this muscle.

Margins (select all that apply) (Note J)

___ Margins cannot be assessed

Invasive Carcinoma

___ Margins uninvolved by invasive carcinoma

Distance from closest margin: ___ mm

Specify margin: _____

___ Cannot be determined (explain): _____

___ Margin(s) positive for invasive carcinoma

Specify margin(s): _____

___ Cannot be determined (explain): _____

+ For positive margins, specify extent (focal, minimal/moderate, or extensive):

+ Anterior: _____

+ Posterior: _____

+ Superior: _____

+ Inferior: _____

+ Medial: _____

+ Lateral: _____

+ Other (specify margin: _____): _____

Note: Margin status is listed as "positive" if there is ink on carcinoma (ie, the distance is 0 mm). If the margin is not positive, then a distance from the margin may be listed. Distances can be specific measurements or expressed as greater than or less than a measurement.

DCIS

___ DCIS not present

___ Margins uninvolved by DCIS

Distance from closest margin: ___ mm

Specify margin: _____

___ Cannot be determined (explain): _____

___ Margin(s) positive for DCIS

Specify margin(s): _____

___ Cannot be determined (explain): _____

+ For positive margins, specify extent (focal, minimal/moderate, or extensive):

- + Anterior: _____
- + Posterior: _____
- + Superior: _____
- + Inferior: _____
- + Medial: _____
- + Lateral: _____
- + Other (specify margin: _____): _____

Note: Margin status is listed as "positive" if there is ink on carcinoma (ie, the distance is 0 mm). If the margin is not positive, then a distance from the margin may be listed. Distances can be specific measurements or expressed as greater than or less than a measurement.

Lymph Nodes (required only if lymph nodes are present in the specimen) (Note B)

Total number of lymph nodes examined (sentinel and nonsentinel): ____

Number of sentinel lymph nodes examined: ____

Lymph Node Involvement (required only if one or more lymph nodes have tumor cells identified)

Number of lymph nodes with macrometastases (>2 mm): ____

Number of lymph nodes with micrometastases (>0.2 mm to 2 mm and/or >200 cells): ____

Number of lymph nodes with isolated tumor cells (≤0.2 mm and ≤200 cells)[#]: ____

+ Size of largest metastatic deposit: ____

[#] Reporting the number of lymph nodes with isolated tumor cells is required only in the absence of macrometastasis or micrometastasis in other lymph nodes.

Note: The sentinel node is usually the first involved lymph node. In the unusual situation in which a sentinel node is not involved by metastatic carcinoma, but a nonsentinel node is involved, this information should be included in a note.

+ Extranodal Extension

- + ____ Present
- + ____ Not identified
- + ____ Cannot be determined

+ Method of Evaluation of Sentinel Lymph Nodes (select all that apply)

- + ____ Hematoxylin-and-eosin (H&E), 1 level
- + ____ H&E, multiple levels
- + ____ Immunohistochemistry
- + ____ Sentinel lymph node biopsy not performed
- + ____ Other (specify): _____

+ Treatment Effect: Response to Presurgical (Neoadjuvant) Therapy (select all that apply) (Note K)

+ In the Breast

- + ____ No known presurgical therapy
- + ____ No definite response to presurgical therapy in the invasive carcinoma
- + ____ Probable or definite response to presurgical therapy in the invasive carcinoma
- + ____ No residual invasive carcinoma is present in the breast after presurgical therapy

+ In the Lymph Nodes

- + ____ No known presurgical therapy
- + ____ No lymph nodes removed
- + ____ No definite response to presurgical therapy in metastatic carcinoma
- + ____ Probable or definite response to presurgical therapy in metastatic carcinoma
- + ____ No lymph node metastases. Fibrous scarring, possibly related to prior lymph node metastases with pathologic complete response
- + ____ No lymph node metastases and no prominent fibrous scarring in the nodes

+ Data elements preceded by this symbol are not required. However, these elements may be clinically important but are not yet validated or regularly used in patient management.

+ Lymph-Vascular Invasion (Note L)

- + ___ Not identified
- + ___ Present
- + ___ Cannot be determined

+ Dermal Lymph-Vascular Invasion

- + ___ No skin present
- + ___ Not identified
- + ___ Present
- + ___ Cannot be determined

Pathologic Staging (based on information available to the pathologist) (pTNM) (Note M)

The T, N, and (when applicable) M categories with modifiers can be listed on 1 line. Only the applicable T, N, or M category is required for reporting. The definitions need not be included in the final report.

TNM Descriptors (required only if applicable) (select all that apply)

- ___ m (multiple foci of invasive carcinoma)
- ___ r (recurrent)
- ___ y (posttreatment)

Primary Tumor (Invasive Carcinoma) (pT)

- ___ pTX: Primary tumor cannot be assessed
- ___ pT0: No evidence of primary tumor[#]
- ___ pTis (DCIS): Ductal carcinoma in situ[#]
- ___ pTis (LCIS): Lobular carcinoma in situ[#]
- ___ pTis (Paget): Paget disease of the nipple *not* associated with invasive carcinoma and/or carcinoma in situ (DCIS and/or LCIS) in the underlying breast parenchyma[#]

pT1: Tumor ≤20 mm in greatest dimension

- ___ pT1mi: Tumor ≤1 mm in greatest dimension (microinvasion)
- ___ pT1a: Tumor >1 mm but ≤5 mm in greatest dimension
- ___ pT1b: Tumor >5 mm but ≤10 mm in greatest dimension
- ___ pT1c: Tumor >10 mm but ≤20 mm in greatest dimension
- ___ pT2: Tumor >20 mm but ≤50 mm in greatest dimension
- ___ pT3: Tumor >50 mm in greatest dimension

pT4: Tumor of any size with direct extension to the chest wall and/or to the skin (ulceration or skin nodules).

Note: Invasion of the dermis alone does not qualify as pT4.

- ___ pT4a: Extension to chest wall, not including only pectoralis muscle adherence/invasion
- ___ pT4b: Ulceration and/or ipsilateral satellite nodules and/or edema (including peau d'orange) of the skin which do not meet the criteria for inflammatory carcinoma
- ___ pT4c: Both T4a and T4b
- ___ pT4d: Inflammatory carcinoma

[#] For the purposes of this case summary, these categories should only be used in the setting of preoperative (neoadjuvant) therapy for which a previously diagnosed invasive carcinoma is no longer present after treatment.

Regional Lymph Nodes (pN) (choose a category based on lymph nodes received with the specimen; immunohistochemistry and/or molecular studies are not required)

If internal mammary lymph nodes, infraclavicular nodes (level III axillary), or supraclavicular lymph nodes are included in the specimen, consult the AJCC Cancer Staging Manual¹ for additional lymph node categories.

Modifier (required only if applicable)

- ___ (sn): Only sentinel node(s) evaluated. If 6 or more nodes (sentinel or nonsentinel) are removed, this modifier should not be used.

Category (pN)

- pNX: Regional lymph nodes cannot be assessed (eg, previously removed, or not removed for pathologic study)
- pN0: No regional lymph node metastasis identified histologically
- pN0 (i-): No regional lymph node metastases histologically, negative IHC
- pN0 (i+): Malignant cells in regional lymph node(s) no greater than 0.2 mm and no more than 200 cells (detected by H&E or IHC including ITC)
- pN0 (mol-): No regional lymph node metastases histologically, negative molecular findings (reverse transcriptase polymerase chain reaction [RT-PCR])
- pN0 (mol+): Positive molecular findings (RT-PCR), but no regional lymph node metastases detected by histology or IHC
- pN1mi: Micrometastases (greater than 0.2 mm and/or more than 200 cells, but none greater than 2.0 mm).
- pN1a: Metastases in 1 to 3 axillary lymph nodes, at least 1 metastasis greater than 2.0 mm[#]
- pN2a: Metastases in 4 to 9 axillary lymph nodes (at least 1 tumor deposit greater than 2.0 mm)[#]
- pN3a: Metastases in 10 or more axillary lymph nodes (at least 1 tumor deposit greater than 2.0 mm)[#]

[#] Nodes containing only ITCs are excluded from the total positive node count for purposes of N classification but should be included in the total number of nodes evaluated.

Distant Metastasis (pM) (required only if confirmed pathologically in this case)

- pM1: Distant detectable metastasis as histologically proven larger than 0.2 mm

Note: The MX designation has been eliminated from the AJCC/UICC TNM system. Definitions have been modified to exclude clinical information.

+ Additional Pathologic Findings (Note N)

- + Specify: _____

Ancillary Studies

Note: For estrogen receptor (ER), progesterone receptor (PgR), HER2, and Ki67 reporting, the CAP Breast Biomarker Template should be used. Pending biomarker studies should be listed in the Comments section of this report.

+ Microcalcifications (select all that apply) (Note O)

- + Not identified
- + Present in DCIS
- + Present in invasive carcinoma
- + Present in nonneoplastic tissue
- + Other (specify): _____

+ Clinical History (select all that apply) (Note P)

- + The current clinical/radiologic breast findings for which this surgery is performed include:
- + Palpable mass
- + Radiologic finding
- + Mass or architectural distortion
- + Calcifications
- + Other (specify): _____
- + Nipple discharge
- + Other (specify): _____
- + Prior history of breast cancer
- + Specify site, diagnosis, and prior treatment: _____
- + Prior presurgical (neoadjuvant) therapy for this diagnosis of invasive carcinoma
- + Specify type: _____

+ Comment(s)

+ Data elements preceded by this symbol are not required. However, these elements may be clinically important but are not yet validated or regularly used in patient management.

Explanatory Notes

A. Procedures

The following types of breast specimens and procedures may be reported with the case summary:

Excisions: These procedures resect breast tissue without the intent of removing the entire breast. The nipple is usually not included with excisions. Excisions include specimens designated “partial mastectomies,” “lumpectomies,” and “quadrantectomies.”

- Image-guided localization excisions: Nonpalpable lesions may be localized by mammography, ultrasound, MRI, or radioactive seeds.
- Excisions without image-guided localization: These excisions are generally performed for palpable masses or to excise major ducts behind the nipple to evaluate nipple discharge.

Total Mastectomy: Removal of all breast tissue, generally including the nipple and areola.

- Simple mastectomy: This procedure consists of a total mastectomy without removal of axillary lymph nodes.
- Skin sparing mastectomy: This is a total mastectomy with removal of the nipple and only a narrow surrounding rim of skin.
- Nipple sparing mastectomy: This is a total mastectomy without removal of skin or nipple. The subareolar tissue is examined and the nipple later removed if involved by carcinoma.
- Modified radical mastectomy: This procedure consists of a total mastectomy with an axillary dissection. In the case summary, the breast and lymph node specimens are documented separately. A small portion of pectoralis muscle is sometimes removed.
- Radical mastectomy: This procedure consists of a total mastectomy with removal of the pectoralis major and pectoralis minor muscles as well as axillary contents. This type of specimen and procedure can be indicated on the case summary as “Other.”

The case summary is intended for reporting the patient’s specimen with the largest focus of invasive carcinoma. If additional margin excisions are performed in the same procedure, the findings for these specimens can be included in the margin evaluation. If additional smaller foci of invasive carcinoma are present in the main excision or in margin excisions, the characteristics of these carcinomas (ie, size, histologic type, and grade) should be recorded under “Additional Pathologic Findings.” Additional ancillary studies on smaller foci of carcinoma are recommended if the carcinomas are of different histologic type or grade. If additional margin excisions are performed in a subsequent procedure (eg, on another day), and a larger area of invasive carcinoma is not present, the case summary need not be used.

If a patient has 2 ipsilateral invasive carcinomas removed in 2 separate excisions during the same procedure, the case summary should be used for the larger invasive carcinoma. The pathologic findings for the smaller cancer may be reported without using the case summary. If a patient has 2 ipsilateral invasive carcinomas removed in 2 separate excisions in procedures on different days, the case summary should be used for the larger carcinoma, and the American Joint Committee on Cancer (AJCC) T classification will pertain to this carcinoma. If a patient has bilateral breast carcinomas, the cancers are reported in separate case summaries.

If information from other specimens is included in completing the case summary (eg, the results of hormone receptors from a prior core needle biopsy or the finding of lymph node metastases on a previous lymph node biopsy), then this must be clearly stated in the “Comments” section, and the accession numbers of the other cases should be provided.

The following types of specimens should not be reported by using this protocol:

- Very small incisional biopsies (including core needle biopsies)
- Re-excision of a biopsy site after removal of most of the carcinoma

Specimen sampling for specimens with invasive carcinoma has the following goals¹⁻⁵:

- The clinical or radiologic lesion for which the surgery was performed must be examined microscopically. If the lesion is a nonpalpable imaging finding, the specimen radiograph and/or additional radiologic studies may be necessary to identify the lesion. When practical, the entire lesion, or the entire area with the imaging finding, should be submitted in a sequential fashion for histologic examination.
- If the specimen consists predominantly of DCIS with microinvasion, complete submission of the entire specimen, or at a minimum the entire grossly involved area, is recommended to identify additional areas of invasion and/or lymph-vascular invasion.
- All other gross lesions in the specimen must be sampled.
- Each designated margin must be evaluated for involvement by invasive carcinoma and DCIS. If the specimen is received sectioned or fragmented, this should be noted, as this will limit the ability to evaluate the status of margins.

Tissue may be taken for research studies or assays that do not involve the histologic examination of the tissue (eg, reverse transcriptase polymerase chain reaction [RT-PCR]) only when taken in such a way as to not compromise the evaluation of the invasive carcinoma and lymph nodes for prognostic factors and margin status.

It is preferable that the area of carcinoma be removed in a single intact specimen. If the specimen has been incised or is fragmented, then it may not be possible to accurately assess margins. If invasive carcinoma is present in more than 1 fragment, it may be difficult or impossible to determine the pathologic size of the invasive carcinoma or the number of invasive carcinomas present. Breast imaging correlation is recommended for these cases. When specimen fragmentation limits the evaluation of tumor size and/or margins, this information should be included under “Additional Pathologic Finding.”

The size of all specimens in 3 dimensions should be documented in the gross description. It is optional to also include specimen sizes in the final diagnosis. The volume of tissue removed can be helpful in estimating the extent of carcinoma present and determining the likely volume of tissue that would need to be removed to achieve tumor-free margins.

If separate oriented margin specimens are excised, the results of the final margin status can be included under “Margins” in the case summary. If not oriented, the findings can be reported under “Additional Pathologic Findings.”

B. Lymph Node Sampling and Reporting

Most patients with invasive carcinoma will have lymph nodes sampled.

Types of lymph nodes:

- **Sentinel lymph nodes** are identified by the surgeon by uptake of radiotracer or dye or both. Adjacent palpable nonsentinel nodes may also be removed.
- **Axillary lymph nodes** are removed by en bloc resection of axillary tissue. The nodes are divided into levels: I (low-axilla: lateral to the lateral border of the pectoralis minor muscle); II (mid-axilla: between the medial and lateral borders of the pectoralis minor muscle and the interpectoral [Rotter’s] lymph nodes); and III (apical axilla or infraclavicular nodes: medial to the medial margin of the pectoralis minor muscle and inferior to the clavicle). A surgeon may choose to remove 1 or more of these levels. Levels I and II are typically removed in the axillary dissection, with level III nodes only removed if considered suspicious by the surgeon

intraoperatively. Level III nodes must be specifically identified, as there are additional AJCC N categories for these nodes.

- **Intramammary nodes** are present within breast tissue and are most commonly found in the upper outer quadrant. Intramammary nodes may rarely be sentinel lymph nodes. These nodes are included with axillary nodes for AJCC N classification.
- **Internal mammary nodes, supraclavicular nodes, and infraclavicular nodes** are rarely removed for breast cancer staging. If metastases are present in these nodes, there are specific AJCC N categories (see *AJCC Cancer Staging Manual*⁶).

Lymph node sampling:

- **Grossly positive nodes:** The size of grossly positive nodes should be recorded. One section to include any areas suggestive of extranodal invasion is sufficient. Cancerous nodules in the axillary fat adjacent to the breast, without histologic evidence of residual lymph node tissue, are classified as regional lymph node metastasis.
- **Grossly negative nodes:** Sampling must be adequate to detect all macrometastases, as they are known to have prognostic importance (ie, all metastatic deposits >2 mm). Thus, each node should be thinly sliced along the long axis of the node at 2 mm, and all slices should be submitted for microscopic examination. At least 1 representative hematoxylin-and-eosin (H&E) level must be examined. Additional methods of sampling, such as additional H&E levels or immunohistochemical studies, may detect isolated tumor cells or micrometastases. However, the clinical impact on outcome of these small metastases is minimal.⁷

The nodes must be submitted in such a way that every node can be evaluated and counted separately.

Reverse transcriptase polymerase chain reaction has been developed as an alternative method for examining lymph nodes.^{8,9} The tissue used for this assay cannot be examined microscopically. All macrometastases must be identified histologically. Therefore, nodal tissue can only be used for other assays if all macrometastases can be identified by H&E examination. False-positive and false-negative results can occur with RT-PCR. The significance of a positive RT-PCR result for a histologically negative lymph node is unknown.

Reporting lymph nodes:

- **Number of nodes examined:** The total number of nodes includes sentinel nodes, nonsentinel nodes, nodes from axillary dissections, and intramammary nodes. When the number of sentinel and nonsentinel nodes removed is less than 6 nodes, the AJCC “sn” modifier is used.
- **Size of metastases:** Metastases are classified into 3 groups:
 - Isolated tumor cell clusters (ITCs) are defined as single cells or small clusters of cells not larger than 0.2 mm and no more than 200 cells in a single cross-section, usually with no histologic evidence of malignant activity (eg, proliferation or stromal reaction).¹⁰ If morphologic techniques (either H&E or immunohistochemistry) are used to detect ITCs, the regional lymph nodes should be designated as pN0(i+) or pN0(i-), as appropriate. Isolated tumor cells are not included in the total number of positive nodes for N classification.
 - Micrometastases measure more than 0.2 mm, but not more than 2 mm, and/or comprise more than 200 cells in a single cross-section. If only micrometastases are present, the N classification is pN1mi. If at least 1 macrometastasis is present, nodes with micrometastases are included in the total node count for N classification.
 - Macrometastases measure more than 2 mm.

In most cases, if metastases are present, the sentinel node will be involved. In rare cases, only nonsentinel nodes contain metastases. These cases can occur if the true sentinel node is completely replaced by tumor (and therefore is not detected by radioactive tracer or dye), if there is unusual lymphatic drainage, or if there is failure of the technique to identify the node. This finding should be included in the report.

In some cases, the best N classification can be difficult to determine (Figure 1).

Figure 1. Classification of Lymph Node Metastases. A. Multiple clusters of tumor cells. Classification is based on the size of the largest contiguous cluster of tumor cells. The distance between clusters should not be included in the size measurement. However, if the overall volume of tumor is similar to the next highest nodal category, it is recommended that the pathologist use his or her judgment to assign the best N category and to include the reason for the difficulty in classification in a note. B. Dispersed pattern of lymph node metastasis. Some carcinomas, in particular lobular carcinomas, metastasize as single cells and do not form cohesive clusters. In such cases, the “size” of the metastasis is difficult to determine. If more than 200 tumor cells are present in 1 cross-section of the node, then the category of isolated tumor cells should not be used. If there is difficulty in assigning the N classification, it is recommended that the reason be provided in a note. C. Extranodal invasion. The area of invasion outside the lymph node capsule is included in the overall size of the lymph node metastasis. The size of the metastasis includes the tumor cells and the desmoplastic response (ie, the cells do not need to be contiguous, but the cells plus fibrosis should be contiguous). The finding of extranodal invasion is also reported. D. Cancerous nodules in axillary fat. Areas of carcinoma invading into the stroma in axillary adipose tissue, without residual nodal tissue, are considered to be positive lymph nodes. However, if there is surrounding breast tissue or ductal carcinoma in situ, then the invasive carcinoma should be classified as an invasive carcinoma and not as a lymph node metastasis.

- **Multiple clusters of tumor cells within a lymph node (Figure 1, A):** The “size” of the metastatic deposit for N classification is based on the largest contiguous cluster of tumor cells. However, when the overall volume of tumor is similar to that of the higher nodal category (eg, a node with 9 clusters of tumor cells, each measuring 1 mm), then the pathologist must use his or her judgment in assigning the N category. The size and number of cells used for AJCC classification are meant to be guidelines and not absolute cutoffs. It is recommended that the reason for the difficulty in assigning the N classification be stated in a note.
- **Dispersed pattern of lymph node metastasis (Figure 1, B):** Some invasive carcinomas, particularly lobular carcinomas, may metastasize as individual tumor cells and not as cohesive clusters. It can be difficult to estimate the volume of tumor present for N classification. To avoid underclassification of such cases, an upper

limit of 200 cells in 1 node cross-section for “isolated tumor cells” is recommended. Pathologist judgment is required to determine the best N classification.

- **Extranodal (or extracapsular) tumor invasion (Figure 1, C):** Metastatic carcinoma may invade through the lymph node capsule into adjacent adipose tissue. This finding correlates with the clinical impression of fixed or matted nodes when extensive and is a risk factor for recurrence. Extranodal extension should be included when determining the size of a lymph node metastasis. The size of the metastasis includes the tumor cells and the surrounding desmoplastic response (ie, the tumor cells need not be touching). Tumor within lymphatic spaces in the axillary tissue without invasion of adipose tissue is not considered extranodal invasion.
- **Cancerous nodules in axillary adipose tissue (Figure 1, D):** Metastatic carcinoma can completely replace a lymph node. Foci of invasive carcinoma in axillary adipose tissue can be counted as positive lymph nodes. There must be stromal invasion, and carcinoma limited to lymphatic channels is not included. If the carcinoma is surrounded by breast tissue and/or DCIS is present, the area of invasion is more likely to be a carcinoma arising in axillary breast tissue and should not be counted as metastatic carcinoma to a lymph node.
- **Nodes after neoadjuvant therapy:** The response of metastatic carcinoma in lymph nodes after treatment is an important prognostic factor. In addition to the information described above, evidence of treatment response (eg, small tumor deposits within an area of fibrosis) should also be reported (see Note K).

C. Tumor Site

The site of an invasive carcinoma is helpful to document, when provided by the surgeon, breast imaging, or previous pathology report, to correlate with prior studies (eg, a core needle biopsy) or with future biopsies or cancer events. The site can be indicated by quadrant and/or by a clock position.

The approximate tumor site can be determined in a mastectomy. However, it is sometimes difficult to correlate exactly with the position as determined in vivo because of differences in how the specimen would be positioned on the chest wall (ie, the skin ellipse may be horizontal or point to the axilla). It is helpful to locate the carcinoma with respect to the clinical site or imaging site, when possible.

If the patient has undergone presurgical (neoadjuvant) therapy and there is no residual invasive carcinoma, the tumor site refers to the location of the prior invasive carcinoma (ie, the tumor bed).

D. Tumor Size (Size of Invasive Carcinoma)

The size of an invasive carcinoma is an important prognostic factor. The single greatest dimension of the largest invasive carcinoma is used to determine T classification (Figure 2, A through F). The best size for AJCC T classification should use information from imaging, gross examination, and microscopic evaluation. Visual determination of size is often unreliable, as carcinomas often blend into adjacent fibrous tissue. The size by palpation of a hard mass correlates better with invasion of tumor cells into stroma with a desmoplastic response. Sizes should be measured to the nearest millimeter. In some cases, the size may be difficult to determine.

Figure 2. Determining the size of an invasive carcinoma. A. Invasive carcinoma with surrounding ductal carcinoma in situ (DCIS). The size only includes the area of the invasive carcinoma and does not include the adjacent DCIS. The size should be measured to the closest 1 mm. B. Small invasive carcinoma with prior core needle biopsy. The size of the carcinoma in the core needle biopsy should not be added to the size of the carcinoma in the excisional specimen, as this will generally overestimate the true size. The best size for classification must take into consideration the largest dimension of the carcinoma in both specimens as well as the size by imaging before the core needle biopsy. C. Small invasive carcinomas with adjacent biopsy site changes. In some excisional specimens, a small carcinoma will be present adjacent to a relatively large area of biopsy site changes. The actual size cannot be determined with certainty. The size in the core needle biopsy, in the excisional specimen, and by imaging should be considered to determine the best size for classification. D. Multiple invasive carcinomas. If multiple carcinomas are present, the size of the largest invasive carcinoma is used for T classification. The modifier “m” is used to indicate that multiple invasive carcinomas are present. E. Multiple invasive carcinomas in close proximity. It may be difficult to distinguish multiple adjacent carcinomas from one large invasive carcinoma. Careful examination of the specimen with submission of tissue between grossly evident carcinomas is essential. Correlation with imaging findings can be helpful. Generally, microscopic size confirmation of the largest grossly identified invasive carcinoma is used for T classification. F. Invasive carcinomas that have been transected. If an invasive carcinoma has been transected and is present in more than 1 tissue fragment, the sizes in each fragment should not be added together, as this may overestimate the true size. In many cases, correlation with the size on breast imaging will be helpful to choose the best size for classification. In other cases, the pathologist will need to use his or her judgment in assigning an AJCC T category.

Invasive carcinoma and DCIS (Figure 2, A): The size measurement includes only the largest area of contiguous invasion of stroma. Surrounding DCIS is not included in the size measurement.

Small invasive carcinoma with adjacent biopsy site changes (Figure 2, B and C): If the invasive carcinoma in the excision is small (ie, ≤ 10 mm) and is adjacent to a prior biopsy site, it is possible that the original size of the carcinoma was larger before biopsy. In such cases it is helpful to compare the largest size on the previous biopsy with the size of the tumor by imaging before biopsy to determine the best size for T classification. However, the sizes on the biopsy and in the excision should not be added together, as this will generally overestimate the size of the carcinoma. Generally, the larger of the sizes as determined from the core biopsy or excision is used for T classification.

Multiple invasive carcinomas (Figure 2, D): The size of the largest carcinoma is used for T classification. The sizes of multiple invasive carcinomas should not be added together. The modifier “m” is used to indicate the presence of multiple invasive carcinomas.

Multiple invasive carcinomas in close proximity (Figure 2, E): It can sometimes be difficult to distinguish a single invasive carcinoma from multiple carcinomas very close to one another. Careful gross examination and examination of tissue between grossly evident carcinomas are required. Contiguous and uniform tumor density in the intervening tissue between 2 macroscopic carcinomas is required to use the combined overall size for T classification. Correlation with imaging can also be helpful. In some cases, diffusely invasive carcinoma (eg, lobular carcinoma) is not easily defined by gross examination or by imaging. The extent of invasion may be indicated by the number of blocks involved and/or the involvement of opposing margins. In some cases, the pathologist will need to use his or her best judgment in assigning the T classification.

Invasive carcinomas that have been transected (Figure 2, F): If an invasive carcinoma is transected during a procedure and is present in more than 1 fragment of tissue, it may be difficult or impossible to determine the size and/or the number of carcinomas present. If the carcinoma is present at the margin of the resection over a broad front by macroscopic examination, the carcinoma could be coded as pTX because the total extent of tumor cannot be assessed. Alternatively, a minimal T size could be provided with a notation that the actual size may be larger. The sizes in multiple specimens of a transected carcinoma should not be added together. In such cases, the size on breast imaging may be helpful in determining the best T classification. Size should always be determined before tissue is taken for clinical assays or for investigational studies.

DCIS with microinvasion: Microinvasion is defined by the AJCC as invasion measuring 1 mm or less in size. If more than 1 focus of microinvasion is present, the number of foci present, an estimate of the number, or a note that the number of foci is too numerous to quantify should be reported. In some cases, immunoperoxidase studies for myoepithelial cells may be helpful to document areas of invasion and the size of the invasive foci.

E. Histologic Type

This protocol applies to all invasive carcinomas of the breast. The World Health Organization (WHO) classification of breast carcinoma is presented below, although the protocol does not preclude the use of other classifications or histologic types. Carcinomas may be classified based on the H&E appearance without the use of immunohistochemical studies.

A modified list is presented in the protocol, based on the most frequent types of invasive carcinomas and terminology that is in widespread usage. The modified list is intended to capture the majority of tumors and reduce the classification of tumors being reported as “other.” The WHO classification is presented for completeness.

WHO Classification of Invasive Carcinoma of the Breast¹¹

Microinvasive carcinoma

Invasive ductal carcinoma, not otherwise specified (NOS)

 Mixed type carcinoma

 Pleomorphic carcinoma

 Carcinoma with osteoclastic giant cells

 Carcinoma with choriocarcinomatous features

 Carcinoma with melanotic features

Invasive lobular carcinoma

Tubular carcinoma

Invasive cribriform carcinoma
 Medullary carcinoma
 Mucinous carcinomas and other tumors with abundant mucin
 Mucinous carcinoma
 Cystadenocarcinoma and columnar cell mucinous carcinoma
 Signet-ring cell carcinoma
 Neuroendocrine tumors
 Solid neuroendocrine carcinoma
 Atypical carcinoid tumor
 Small cell/oat cell carcinoma
 Large cell neuroendocrine carcinoma
 Invasive papillary carcinoma
 Invasive micropapillary carcinoma
 Apocrine carcinoma
 Metaplastic carcinomas
 Pure epithelial metaplastic carcinomas
 Squamous cell carcinoma
 Adenocarcinoma with spindle cell metaplasia
 Adenosquamous carcinoma
 Mucoepidermoid carcinoma
 Mixed epithelial/mesenchymal metaplastic carcinomas
 Lipid-rich carcinoma
 Secretory carcinoma
 Oncocytic carcinoma
 Adenoid cystic carcinoma
 Acinic cell carcinoma
 Glycogen-rich clear cell carcinoma
 Sebaceous carcinoma
 Inflammatory carcinoma: defined clinically as erythema and edema involving at least one-third of the breast.
 Clinical features of inflammatory carcinoma must be present in order to classify a carcinoma as T4d.

F. Histologic Grade

All invasive breast carcinomas should be graded.¹² The Nottingham combined histologic grade (Elston-Ellis modification of Scarff-Bloom-Richardson grading system) should be used for reporting. Within each stage grouping there is a relation between histologic grade and outcome.

The Nottingham combined histologic grade evaluates the amount of tubule formation, the extent of nuclear pleomorphism, and the mitotic count (or mitotic rate). Each variable is given a score of 1, 2, or 3, and the scores are added to produce a grade. The mitotic score is determined by the number of mitotic figures found in 10 consecutive high-power fields (HPF) in the most mitotically active part of the tumor. Only clearly identifiable mitotic figures should be counted; hyperchromatic, karyorrhectic, or apoptotic nuclei are excluded. Because of variations in field size, the HPF size must be determined for each microscope and the appropriate point score determined accordingly. It is recommended that the size be measured by using a micrometer. However, the diameter of an HPF can also be calculated by using the method below.

Measuring the Size of a High-Power Field (HPF) With a Ruler

Use a clear ruler to measure the diameter of a low-power field. This number can be used to calculate a constant based on the following formula:

$$\text{Eyepiece Magnification} \times \text{Objective Magnification} \times \text{Microscopic Field Diameter} \\ = \text{A Constant}$$

When the value of the constant is known, the diameter of an HPF can be calculated for other objectives by using the following formula:

Unknown Field Diameter = Constant/(Eyepiece Magnification x Objective Magnification)

Half of the field diameter is the radius of the field (r), which can then be used to calculate the area of the HPF:

$$3.1415 \times r^2 = \text{Area of Microscopic Field}$$

If the microscopic field diameter or the area of the field is known, Table 1 can be used to determine the number of mitoses corresponding to different scores.

Table 1. Score Categories According to Field Diameter and Mitotic Count

Scoring Categories of Mitotic Counts				
Field diameter (mm)	Area (mm ²)	Number of mitoses per 10 fields corresponding to:		
		Score 1	Score 2	Score 3
0.40	0.125	≤4	5 to 9	≥10
0.41	0.132	≤4	5 to 9	≥10
0.42	0.139	≤5	6 to 10	≥11
0.43	0.145	≤5	6 to 10	≥11
0.44	0.152	≤5	6 to 11	≥12
0.45	0.159	≤5	6 to 11	≥12
0.46	0.166	≤6	7 to 12	≥13
0.47	0.173	≤6	7 to 12	≥13
0.48	0.181	≤6	7 to 13	≥14
0.49	0.189	≤6	7 to 13	≥14
0.50	0.196	≤7	8 to 14	≥15
0.51	0.204	≤7	8 to 14	≥15
0.52	0.212	≤7	8 to 15	≥16
0.53	0.221	≤8	9 to 16	≥17
0.54	0.229	≤8	9 to 16	≥17
0.55	0.238	≤8	9 to 17	≥18
0.56	0.246	≤8	9 to 17	≥18
0.57	0.255	≤9	10 to 18	≥19
0.58	0.264	≤9	10 to 19	≥20
0.59	0.273	≤9	10 to 19	≥20
0.60	0.283	≤10	11 to 20	≥21
0.61	0.292	≤10	11 to 21	≥22
0.62	0.302	≤11	12 to 22	≥23
0.63	0.312	≤11	12 to 22	≥23
0.64	0.322	≤11	12 to 23	≥24
0.65	0.332	≤12	13 to 24	≥25
0.66	0.342	≤12	13 to 24	≥25
0.67	0.353	≤12	13 to 25	≥26

Scoring Categories of Mitotic Counts				
Field diameter (mm)	Area (mm ²)	Number of mitoses per 10 fields corresponding to:		
		Score 1	Score 2	Score 3
0.68	0.363	≤13	14 to 26	≥27
0.69	0.374	≤13	14 to 27	≥ 28

G. Tumor Focality (Single or Multiple Foci of Invasive Carcinoma)

Focality need not be specifically stated if there is only a single area of invasive carcinoma. If multiple invasive carcinomas are present, focality should be reported. Patients with multiple foci of invasion may be divided into the following 6 groups:

- **Extensive carcinoma in situ (CIS) with multiple foci of invasion (Figure 3, A).** Extensive DCIS is sometimes associated with multiple areas of invasion. The invasive carcinomas are usually similar in histologic appearance and immunophenotype, unless the DCIS shows marked heterogeneity. This is the most common etiology of multiple invasive carcinomas.
- **Invasive carcinoma with smaller satellite foci of invasion (Figure 3, B).** A large carcinoma is sometimes surrounded by smaller adjacent foci of invasion. In such cases, the appearance of multiple foci may be due to irregular extensions of the carcinoma into stroma, which in 2 dimensions give the appearance of multiple foci. In such cases, the smaller foci are usually identical in histologic appearance and immunophenotype to the dominant carcinoma.
- **Invasive carcinoma with extensive lymph-vascular invasion (LVI) (Figure 3, C).** Additional foci of invasion may arise from areas of LVI (ie, an intramammary metastasis). The multiple carcinomas are usually identical in histologic appearance and immunophenotype. The origin of satellite skin nodules classified as T4b is generally due to invasion arising from foci of dermal lymph-vascular invasion.
- **Multiple biologically separate invasive carcinomas (Figure 3, D).** Some patients have multiple, synchronous, biologically independent carcinomas. Patients with germ-line mutations are at increased risk for developing multiple carcinomas. The carcinomas may or may not be similar in appearance and immunophenotype.
- **Invasive carcinomas after neoadjuvant therapy (Figure 3, E).** Cancers with a significant response to chemotherapy typically present as multiple residual foci within a fibrotic tumor bed (see Note K). The foci of invasion are usually identical in appearance and immunophenotype.
- **Transection of a single carcinoma into multiple fragments (Figure 3, F).** If invasive carcinoma is present in multiple fragments of a fragmented specimen, transection of 1 carcinoma should be considered. Correlation with clinical and imaging findings can sometimes be helpful to determine the best size for T classification and to determine whether or not multiple foci were present.

Figure 3. Multiple Invasive Carcinomas. A. Extensive carcinoma in situ with multiple foci of invasion. The invasive carcinomas are usually similar in histologic appearance and immunoprofile unless the ductal carcinoma in situ (DCIS) shows marked heterogeneity. B. Invasive carcinoma with smaller satellite foci. The smaller foci are generally within 1 to 5 mm of the main carcinoma and are most likely due to extensions of the main carcinoma that would be connected in another plane of section. The carcinomas are usually identical in appearance and immunoprofile. C. Invasive carcinoma with extensive lymph-vascular invasion. Areas of lymph-vascular invasion can give rise to additional foci of invasive carcinoma (ie, intramammary metastasis). The carcinomas are usually identical in appearance and immunoprofile. D. Multiple biologically separate invasive carcinomas. These carcinomas are usually widely separated and may be histologically and immunophenotypically distinct. E. Invasive carcinomas after presurgical (neoadjuvant) therapy. If there is a marked response to treatment, multiple foci of carcinoma may be scattered over a fibrotic tumor bed. The residual carcinoma is usually similar in appearance and immunoprofile to the pretreatment carcinoma, but in some cases alterations due to treatment may be present. F. Transection of a single carcinoma into multiple fragments. If a carcinoma is transected during excision, it may be difficult to determine if 1 or multiple carcinomas are present. The carcinomas should be identical in appearance and immunoprofile.

Features pertaining to a specific cancer (ie, histologic type, grade, size, and the results of ER, PgR, and HER2 studies) should be provided for the largest invasive carcinoma in the case summary. If smaller carcinomas differ in histologic type or grade, this information should be included under “Additional Pathologic Findings,” and additional ancillary tests are recommended for these carcinomas. Features pertaining to all carcinomas (eg, margins, lymph node status) can be reported in the body of the case summary.

Patients with multiple grossly evident invasive carcinomas have a higher risk of having lymph node metastases.¹⁴ However, it has not been shown that multiple invasive carcinomas increase the risk of distant metastases for patients with lymph node-negative disease.

The overall AJCC T classification is based on the carcinoma with the highest individual T classification. If there are bilateral cancers, the stage is based on the carcinoma with the higher stage. Cases with multiple foci of invasive carcinoma are indicated by the modifier “m” in AJCC classification to distinguish them from cases with a single focus of invasion.

H. Ductal Carcinoma In Situ

Ductal carcinoma in situ associated with invasive carcinoma increases the risk of local recurrence for women undergoing breast conserving surgery. It is more important to report the features of DCIS when in situ disease is predominant (eg, cases of DCIS with microinvasion or extensive DCIS associated with T1a carcinoma). If DCIS is a minimal component of the invasive carcinoma, the features of the DCIS have less clinical relevance. Therefore, most of the reporting elements for DCIS are optional and should be used at the discretion of the pathologist.

The pathology report should specify whether extensive DCIS is present. Extensive intraductal component (EIC)-positive carcinomas are defined in 2 ways (Figure 4, A through D)¹⁵:

Figure 4. Extensive Intraductal Component (EIC). A. Extensive intraductal component (EIC)-positive carcinomas are defined by the following criteria: (1) $\geq 25\%$ of the area within the invasive carcinoma is ductal carcinoma in situ (DCIS) and (2) DCIS is also present outside the area of invasive carcinoma. B. EIC-positive carcinomas also include carcinomas in which DCIS is associated with a “small” (approximately 10 mm or less) invasive carcinoma or carcinomas. C. EIC-negative carcinomas do not fulfill the criteria for being positive for EIC. D. Some carcinomas do not strictly fulfill the criteria for EIC but are associated with extensive DCIS in the surrounding tissue. In such cases it is helpful to provide some measure of the extent of DCIS in the specimen.

1. Ductal carcinoma in situ is a major component within the area of invasive carcinoma (approximately 25%) and DCIS is also present in the surrounding breast parenchyma.

2. There is extensive DCIS associated with a small (~10 mm or less) invasive carcinoma (ie, the invasive carcinoma is too small for DCIS to comprise 25% of the area).

Extensive intraductal component-positive carcinomas are associated with an increased risk of local recurrence when the surgical margins are not evaluated or focally involved. The finding of EIC positivity has less significance when DCIS does not extend close to margins.

In some cases, extensive DCIS can be present outside the area of invasive carcinoma although the carcinoma does not technically fulfill the criteria for EIC positivity. In such cases, quantification of the amount of DCIS present is helpful for planning radiation therapy.

The extent of DCIS will be most relevant for cases of extensive DCIS with microinvasion and least relevant for large EIC-negative invasive carcinomas. Methods for estimating the extent of DCIS include directly measuring the lesion when confined to a single histologic slide, determining size by submitting the entire specimen in sequence and in sections of uniform thickness, or counting the number of blocks with DCIS. The College of American Pathologists (CAP) DCIS protocol¹⁶ provides additional information on determining the extent of DCIS.

Architectural Pattern of DCIS

The architectural pattern has traditionally been reported for DCIS. However, nuclear grade and the presence of necrosis are more predictive of clinical outcome.

Nuclear Grade of DCIS

The nuclear grade of DCIS is determined using 6 morphologic features (Table 1).¹⁷

Table 2. Nuclear Grade of Ductal Carcinoma in Situ

Feature	Grade I (Low)	Grade II (Intermediate)	Grade III (High)
Pleomorphism	Monotonous (monomorphic)	Intermediate	Markedly pleomorphic
Size	1.5 to 2 x the size of a normal red blood cell or a normal duct epithelial cell nucleus	Intermediate	>2.5 x the size of a normal red blood cell or a normal duct epithelial cell nucleus
Chromatin	Usually diffuse, finely dispersed chromatin	Intermediate	Usually vesicular with irregular chromatin distribution
Nucleoli	Only occasional	Intermediate	Prominent, often multiple
Mitoses	Only occasional	Intermediate	May be frequent
Orientation	Polarized toward luminal spaces	Intermediate	Usually not polarized toward the luminal space

Necrosis

The presence of necrosis is correlated with the finding of mammographic calcifications (ie, most areas of necrosis will calcify). Ductal carcinoma in situ that presents as mammographic calcifications often recurs as calcifications. Necrosis can be classified as follows:

- **Central (“comedo”)**: The central portion of an involved ductal space is replaced by an area of expansive necrosis that is easily detected at low magnification. Ghost cells and karyorrhectic debris are generally present. Although central necrosis is generally associated with high-grade nuclei (ie, comedo DCIS), it can also occur with DCIS of low or intermediate nuclear grade.
- **Focal**: Small foci, indistinct at low magnification, or single cell necrosis.

Necrosis should be distinguished from secretory material, which can also be associated with calcifications, but does not include nuclear debris.

I. Macroscopic and Microscopic Extent of Tumor

Breast cancers can invade into the overlying skin or into the chest wall, depending on their size and location. Extension into skin and muscle is used for AJCC classification, and these findings may be used for making decisions about local treatment. If skin or muscle are part of a specimen, their presence should always be included in the gross description and the relationship of these structures to the carcinoma reported in the final diagnosis. The extent of associated DCIS is important for determining the type of surgery that will be necessary to obtain free margins.

Skin

There are multiple ways that breast carcinoma can involve the skin:

- DCIS involving nipple skin (Paget disease of the nipple) (Figure 5, A): DCIS can extend from the lactiferous sinuses into the contiguous skin without crossing the basement membrane. This finding does not change the T classification of the invasive carcinoma.
- Invasive carcinoma invading into dermis or epidermis, without ulceration (Figure 5, B): Skin invasion correlates with the clinical finding of a carcinoma fixed to the skin and may be associated with skin or nipple retraction. This finding does not change the T classification.
- Invasive carcinoma invading into dermis and epidermis with skin ulceration (Figure 5, C): In the past, skin ulceration was associated with very large, locally advanced carcinomas. However, skin ulceration can also be associated with superficially located small carcinomas. It is unknown if skin involvement confers a worse prognosis as compared to carcinomas of similar size without skin invasion. Carcinomas with skin ulceration are classified as T4b.
- Ipsilateral satellite skin nodules (Figure 5, D): An area of invasive carcinoma within the dermis, separate from the main carcinoma, is usually associated with lymph-vascular invasion. The satellite nodules should be macroscopically evident and confirmed microscopically. This finding is classified as T4b. The clinical significance of incidental microscopic satellite nodules in the dermis has not been investigated.
- Dermal lymph-vascular invasion (Figure 5, E): Carcinoma present within lymphatic spaces in the dermis is often correlated with the clinical features of inflammatory carcinoma (diffuse erythema and edema involving one-third or more of the breast), and such cases would be classified as T4d. In the absence of the clinical features of inflammatory carcinoma, this finding remains a poor prognostic factor but is insufficient to classify a cancer as T4d. This finding is separately documented under “Dermal Lymph-Vascular Invasion.”

Figure 5. Invasive Carcinoma: Skin Involvement. A. Ductal carcinoma in situ (DCIS) involving nipple skin (Paget disease of the nipple) associated with an invasive carcinoma. DCIS can traverse the lactiferous sinuses into the epidermis without crossing a basement membrane. This finding does not change the T classification of an underlying invasive carcinoma. B. Invasive carcinoma invading into dermis or epidermis, without ulceration. This finding does not change the T classification of the invasive carcinoma. C. Invasive carcinoma invading into dermis and epidermis with skin ulceration. This carcinoma would be classified as T4b, unless additional features warrant classification as T4c (chest wall invasion) or T4d (inflammatory carcinoma). D. Ipsilateral satellite skin nodules. An area of invasive carcinoma in the skin, separate from the main carcinoma, is usually associated with lymph-vascular invasion. This finding is classified as T4b, unless additional features warrant classification as T4c (chest wall invasion) or T4d (inflammatory carcinoma). E. Dermal lymph-vascular invasion. If carcinoma within lymphatic spaces in the dermis is correlated with the clinical features of inflammatory carcinoma (diffuse erythema and edema involving one-third or more of the breast), the carcinoma is classified as T4d. If clinical signs are not present, this finding does not change the T classification, but is an indicator of a poor prognosis.

Muscle

Skeletal muscle may be present at the deep/posterior margin. The presence of muscle documents that the excision has extended to the deep fascia. Invasion into skeletal muscle should be reported, as this finding may be used as an indication for postmastectomy radiation therapy.

The skeletal muscle present is generally pectoralis muscle. Invasion into this muscle is not included as T4a. Invasion must extend through this muscle into the chest wall (intercostal muscles or deeper) in order to be classified as T4a. However, chest wall muscles are rarely removed in mastectomy specimens. The T4a classification is generally established with imaging of locally advanced carcinomas.

J. Margins

Whenever feasible, the specimen should be oriented in order for the pathologist to identify specific margins. This is particularly important for excisions less than total mastectomy, where it may be necessary for the surgeon to

excise residual tumor at a specific margin (eg, superior, inferior, medial, lateral, anterior, or deep). Identification of surgical margins also allows measurement of the distance between the carcinoma and specific margins. All identifiable margins should be evaluated for involvement by carcinoma both grossly and microscopically.

Orientation may be done by sutures or clips placed on the specimen surface or by other means of communication between surgeon and pathologist, and should be documented in the pathology report. Margins can be identified in several ways, including the use of multiple colored inks, by submitting the margins in specific cassettes, or by the surgeon submitting each margin as a separately excised specimen. Inks should be applied carefully to avoid penetration deep into the specimen.

Macroscopic or microscopic involvement of surgical margins by invasive carcinoma or DCIS should be noted in the report. If the specimen is oriented, the specific site(s) of involvement should also be reported. When possible, the pathologist should report the distance from the tumor to the closest margin.

If margins are sampled with perpendicular sections, the pathologist should report the distance of the invasive carcinoma and DCIS to the closest margin, whenever possible. Because of the growth pattern of DCIS in the ductal system, a negative but close margin does not ensure the absence of DCIS in the adjacent tissue.

A positive margin requires ink on carcinoma. If the specimen is oriented, the specific site(s) of involvement (eg, superior margin) should also be reported.

The deep margin may be at muscle fascia. If so, the likelihood of additional breast tissue beyond this margin (and therefore possible involvement by DCIS) is extremely small. A deep muscle fascial margin (eg, on a mastectomy specimen) positive for DCIS is unlikely to have clinical significance. However, invasive carcinoma at the deep margin, especially if associated with muscle invasion, is often an indication for postmastectomy radiation.

A superficial (generally anterior) margin may be immediately below the skin, and there may not be additional breast tissue beyond this margin. However, some breast tissue can be left in skin flaps, and the likelihood of residual breast tissue is related to the thickness of the flap.¹⁸

Specimen radiography is important to assess the adequacy of excision. Compression of the specimen should be minimized, as it can severely compromise the ability to assess the distance of the DCIS from the surgical margin. Mechanical compression devices should be used with caution and preferably reserved for nonpalpable lesions that require this technique for imaging (eg, microcalcifications).

It is helpful to report the approximate extent of margin involvement:

- Focal: 1 focal area of carcinoma at the margin, <4 mm
- Minimal/moderate: 2 or more foci of carcinoma at the margin
- Extensive: carcinoma present at the margin over a broad front (>5 mm)

K. Treatment Effect

Patients may be treated with endocrine therapy or chemotherapy before surgical excision (termed presurgical or neoadjuvant therapy). The response of the invasive carcinoma to therapy is a strong prognostic factor for disease-free and overall survival. Special attention to finding and evaluating the tumor bed is necessary for these specimens.¹⁹⁻²¹

Numerous classification systems have been developed to evaluate response.^{19,20} Institutions or treatment protocols may require evaluation by one of these systems. The AJCC stage after treatment is also associated with prognosis. T and N categories determined after treatment are indicated by the prefix “yp.”

Invasive carcinomas with a minor response may show little or no change in size. With greater degrees of response, the carcinoma shows decreased cellularity and may be present as multiple foci of invasion scattered over a larger tumor bed. The AJCC T category is determined by the largest contiguous focus of invasive carcinoma. The “m” modifier is used to indicate that multiple foci of invasive carcinoma are present. The measurement should not include acellular areas of fibrosis within the tumor bed. The inclusion of additional information, such as the distance over which invasive carcinoma is present, the number of foci of invasive

carcinoma, or the number of slides or blocks with invasive carcinoma, may be helpful in estimating the extent of residual disease. If no residual invasive carcinoma is present in the breast, the case summary can be used to report residual DCIS and/or metastatic carcinoma in lymph nodes. If there is no residual carcinoma in the breast or in the lymph nodes, then a CAP protocol case summary need not be used for reporting.

Most carcinomas are of the same grade after treatment. In a few cases, the grade will be higher because of marked nuclear pleomorphism. In very rare cases, the carcinoma will be of lower grade. The prognostic significance of a change in grade after treatment has not been determined.

If negative prior to treatment, it is recommended that ER, PgR, and HER2 be repeated on invasive carcinomas after treatment, as significant changes may occur in a subset of carcinomas, sometimes due to tumor heterogeneity and limited sampling prior to treatment.

L. Lymph-Vascular Invasion

Lymph-vascular invasion (LVI) is associated with local recurrence and reduced survival.²²⁻²⁴ Distinguishing lymphatic channels from blood vessels is unnecessary. Documenting the presence of dermal lymph-vascular invasion is particularly important because of its strong association with the clinical findings of inflammatory breast carcinoma. Strict criteria have been proposed for the diagnosis of LVI²⁵ (Table 3). Lymph-vascular invasion may be seen in stroma between uninvolved lobules and can sometimes be mistaken for DCIS if the cells completely fill the lymphatic space.

Guidelines issued by the St. Gallen International Expert Consensus Conference²⁶ and the National Comprehensive Cancer Network (NCCN)²⁷ include recommendations based on the presence of “extensive” LVI but do not define the term “extensive.” There are conflicting results on the significance of the number of foci of LVI.^{23,24} Pathologists may report the number of foci or the number of blocks with LVI as a measure of extent.

Table 3. Criteria for Lymph-Vascular Invasion (LVI)

1.	LVI must be diagnosed outside the border of the invasive carcinoma. The most common area to find LVI is within 1 mm of the edge of the carcinoma.
2.	The tumor emboli usually do not conform exactly to the contours of the space in which they are found. In contrast, invasive carcinoma with retraction artifact mimicking LVI will have exactly the same shape.
3.	Endothelial cell nuclei should be seen in the cells lining the space.
4.	Lymphatics are often found adjacent to blood vessels and often partially encircle a blood vessel.

Data derived from Rosen.²⁵

M. TNM and Stage Groupings

The tumor-node-metastasis (TNM) staging system maintained collaboratively by the American Joint Committee on Cancer (AJCC) and the International Union Against Cancer (UICC) is recommended.⁶

Pathologic Classification

The pathologic classification of a cancer is based on information acquired before treatment supplemented and modified by the additional evidence acquired during and from surgery, particularly from pathologic examination of resected tissues. The pathologic classification provides additional precise and objective data. Classification of T, N, and M by pathologic means is denoted by use of a lower case “p” prefix (pT, pN, pM).

Pathologic T (pT): The pathologic assessment of the primary tumor (pT) generally is based on resection of the primary tumor generally from a single specimen. Resection of the tumor with several partial removals at the same or separate operations necessitates an effort at reasonable estimates of the size and extension of the tumor to assign the correct or highest pT category. On rare occasions, the tumor size is obtained from a previous core needle biopsy specimen, as the tumor in the core may be larger than the tumor in the excision specimen.

AJCC/UICC definition of inflammatory carcinoma (T4d): Inflammatory carcinoma is a clinical-pathologic entity characterized by diffuse erythema and edema (peau d’orange) involving one-third or more of the skin of the

breast. The skin changes are due to lymphedema caused by tumor emboli within dermal lymphatics, which may or may not be obvious in a small skin biopsy. However, a tissue diagnosis is still necessary to demonstrate an invasive carcinoma in the underlying breast parenchyma or at least in the dermal lymphatics, as well as to determine biological markers, such as ER, PgR, and HER2 status. Tumor emboli in dermal lymphatics without the clinical skin changes described above do not qualify as inflammatory carcinoma. Locally advanced breast cancers directly invading the dermis or ulcerating the skin without the clinical skin changes also do not qualify as inflammatory carcinoma. Thus, the term inflammatory carcinoma should not be applied to neglected locally advanced cancer of the breast presenting late in the course of a patient's disease. The rare case that exhibits all the features of inflammatory carcinoma, but in which skin changes involve less than one-third of the skin, should be classified by the size and extent of the underlying carcinoma.

Pathologic N (pN): The pathologic assessment of regional lymph nodes (pN) ideally requires resection of a minimum number of lymph nodes to assure that there is sufficient sampling to identify positive nodes if present. The recommended number generally does not apply in cases where sentinel node has been accepted as accurate for defining regional node involvement and a sentinel node procedure has been performed. At least 1 node with *presence or absence* of cancer documented by pathologic examination is required for pathologic staging N.

Direct extension of primary tumor into a regional node is classified as node positive. A tumor nodule with a smooth contour in a regional node area is classified as a positive node. The size of the metastasis, not the size of the node, is used for the criterion for the N category.

Specialized pathologic techniques such as immunohistochemistry or molecular techniques may identify limited metastases in lymph nodes that may not have been identified without the use of the special diagnostic techniques. Single tumor cells or small clusters of cells are classified as isolated tumor cells (ITCs). The standard definition for ITCs is a cluster of cells not more than 0.2 mm in greatest diameter. Cases with ITCs only in lymph nodes are classified as pN0. This rule also generally applies to cases with findings of tumor cells or their components by non-morphologic techniques such as flow cytometry or DNA analysis.

AJCC/UICC definition of isolated tumor cells: Isolated tumor cell clusters (ITC) are defined as small clusters of cells not greater than 0.2 mm or single tumor cells, or fewer than 200 cells in a single histologic cross-section. ITCs may be detected by routine histology or by immunohistochemical (IHC) methods. Nodes containing only ITCs are excluded from the total positive node count for purposes of N classification but should be included in the total number of nodes evaluated.

Approximately 1000 tumor cells are contained in a 3-dimensional 0.2-mm cluster. Thus, if more than 200 individual tumor cells are identified as single dispersed tumor cells or as a nearly confluent elliptical or spherical focus in a single histologic section of a lymph node, there is a high probability that more than 1000 cells are present in the lymph node. In these situations, the node should be classified as containing a micrometastasis (pN1mi). Cells in different lymph node cross-sections or longitudinal sections or levels of the block are not added together; the 200 cells must be in a single node profile even if the node has been thinly sectioned into multiple slices. It is recognized that there is substantial overlap between the upper limit of the ITC and the lower limit of the micrometastasis categories due to inherent limitations in pathologic nodal evaluation and detection of minimal tumor burden in lymph nodes. Thus, the threshold of 200 cells in a single cross-section is a guideline to help pathologists distinguish between these 2 categories. The pathologist should use judgment regarding whether it is likely that the cluster of cells represents a true micrometastasis or is simply a small group of isolated tumor cells.

Pathologic M (pM): The pathologic assignment of the presence of metastases (pM1) requires a biopsy positive for cancer at the metastatic site. The designation MX has been eliminated from the AJCC/UICC TNM system. Pathologic M0 is an undefined concept, and the category "pM0" may not be used. Pathologic classification of the absence of distant metastases can only be made at autopsy. Cases with a biopsy of a possible metastatic site that shows ITCs such as circulating tumor cells (CTCs) or disseminated tumor cells (DTCs), or bone marrow micrometastases detected by IHC or molecular techniques, are classified as M0(i+) to denote the uncertain prognostic significance of these findings, and to classify the stage group according to the T and N and M0.

Posttherapy or post-neoadjuvant therapy classification (yTNM): Cases for which systemic and/or radiation therapy are given before surgery (“neoadjuvant”) or for which no surgery is performed may have the extent of disease assessed at the conclusion of the therapy by clinical or pathologic means (if resection performed). This classification is useful to clinicians because the extent of response to therapy may provide important prognostic information to patients and help direct the extent of surgery or subsequent systemic and/or radiation therapy. T and N are classified by using the same categories as for clinical or pathologic staging for the disease type, and the findings are recorded by using the prefix designator “y” (eg, ycT; ycN; ypT; ypN). The “yc” prefix is used for the clinical stage after therapy, and the “yp” prefix is used for the pathologic stage for those cases that have surgical resection after neoadjuvant therapy. The M component should be classified by the M status defined pathologically prior to therapy.

Retreatment classification (rTNM): This classification is assigned when further treatment is planned for a cancer that recurs after a disease-free interval. The original stage assigned at the time of initial diagnosis and treatment does not change when the cancer recurs or progresses. The use of this staging for retreatment or recurrence is denoted with the “r” prefix (rTNM). All information available at the time of retreatment should be used in determining the rTNM stage.

Multiple tumors: When there are multiple simultaneous tumors of the same histology in 1 organ, the tumor with the highest T category is the one selected for classification and staging, and the multiplicity or the number of tumors is indicated in parentheses: for example, T2(m) or T2(5). For simultaneous bilateral cancers in paired organs, the tumors are classified separately as independent tumors in different organs.

Metachronous primaries: Second or subsequent primary cancers occurring in the same organ or in different organs are staged as a new cancer with the TNM system. Second cancers are not staged using the “y” prefix unless the treatment of the second cancer warrants this use.

Residual tumor and surgical margins: The absence or presence of residual tumor after treatment is described by the symbol “R.” cTNM and pTNM describe the extent of cancer in general without consideration of treatment. cTNM and pTNM can be supplemented by the R classification, which deals with the tumor status after treatment. In some cases treated with surgery and/or with neoadjuvant therapy, there will be residual tumor at the primary site after treatment because of incomplete resection or local and regional disease that extends beyond the limit or ability of resection. The presence of residual tumor may indicate the effect of therapy, influence further therapy, and be a strong predictor of prognosis. In addition, the presence or absence of disease at the margin of resection may be a predictor of the risk of recurrent cancer. The presence of residual disease or positive margins may be more likely with more advanced T or N category tumors. The R category is not incorporated into TNM staging itself. However, the absence or presence of residual tumor and status of the margins may be recorded in the medical record and cancer registry.

The R categories for the primary tumor site are:

R0	No residual tumor
R1	Microscopic residual tumor
R2	Macroscopic residual tumor
RX	Presence of residual tumor cannot be assessed

The margin status may be recorded using the following categories:

Negative margins (tumor not present at surgical margin)
 Microscopic positive margin (tumor not identified grossly at the margin, but present microscopically at the margin)
 Macroscopic positive margin (tumor identified grossly at the margin)
 Margin not assessed

Anatomic Stage/Prognostic Groups

Stage 0	Tis	N0	M0
Stage IA	T1 [#]	N0	M0

Stage IB	T0	N1mi	M0
	T1 [#]	N1mi	M0
Stage IIA	T0	N1 ^{##}	M0
	T1 [#]	N1 ^{##}	M0
	T2	N0	M0
Stage IIB	T2	N1	M0
	T3	N0	M0
Stage IIIA	T0	N2	M0
	T1 [#]	N2	M0
	T2	N2	M0
	T3	N1	M0
	T3	N2	M0
Stage IIIB	T4	N0,N1,N2	M0
Stage IIIC	Any T	N3	M0
Stage IV	Any T	Any N	M1

[#] T1 includes T1mi.

^{##} Does not include N1mi.

N. Additional Pathologic Findings

In some cases, additional pathologic findings are important for the clinical management of patients.

If the biopsy was performed for a benign lesion and the invasive carcinoma is an incidental finding, this should be documented. An example would be the finding of DCIS with microinvasion in an excision for a large palpable fibroadenoma.

If there has been a prior core needle biopsy or excisional biopsy, the biopsy site should be sampled and documented in the report. If the intention was to completely re-excite a prior surgical site, the report should document biopsy changes at the margin that could indicate an incomplete excision. This protocol should not be used if the main area of carcinoma has been previously removed and the current specimen is a re-excision of the margins.

If multiple invasive carcinomas are present and differ in histologic type, grade, or the expression of ER, PgR, or HER2, this information should be included as text in this section.

O. Microcalcifications

Cancer found in biopsies performed for microcalcifications will almost always be at the site of the calcifications or in close proximity. The presence of the targeted calcifications in the specimen should be confirmed by specimen radiography. The pathologist must be satisfied that the specimen has been sampled in such a way that the lesion responsible for the calcifications has been examined microscopically. The relationship of the radiologic calcifications to the invasive carcinoma and the DCIS should be indicated.

If calcifications can be seen in the specimen radiograph but not in the initial histologic sections, deeper levels should be examined. If needed, radiographs of the paraffin block(s) may be obtained to detect calcifications remaining in the block(s). If microcalcifications cannot be confirmed by routine microscopic evaluation, polarized light may be helpful, since calcium oxalate crystals are refractile and polarizable but usually clear or tinged yellow in H&E sections. On rare occasions, calcifications do not survive tissue processing or prolonged fixation in formalin. Foreign material can sometimes simulate calcifications (eg, metallic fragments after surgery or trauma).

P. Clinical Information

It is a requirement of The Joint Commission (jointcommission.org) that clinical information be provided for pathology specimens. Relevant clinical information is often necessary for the accurate evaluation of breast specimens and includes:

Patient information:

- Family history of breast or ovarian cancer and/or *BRCA1* or *BRCA2* mutation

- Current pregnancy or lactation
- Prior breast biopsy or surgery (including implants)
- Prior breast cancer diagnosis (type, location in breast, date of diagnosis)
- Prior treatment that could affect the breast:
 - Radiation
 - Chemotherapy (neoadjuvant or adjuvant)
 - Hormonal therapy (eg, tamoxifen, aromatase inhibitors, or oral contraceptives)
- Systemic diseases that may affect the breast (eg, collagen vascular disease, sarcoidosis, Wegener granulomatosis)

Specimen information:

- Type of lesion sampled (may include more than 1 of the following):
 - Palpable mass
 - Nipple discharge
 - Nipple lesion (eg, scaling crust)
 - Imaging finding
 - Mammographic or ultrasound mass: shape of mass (irregular, circumscribed, ill-defined, cystic or solid)
 - Mammographic calcifications
 - Mammographic architectural distortion
 - Prior core needle biopsy site, with or without a clip, with or without residual radiologic or clinical lesion
 - MRI-detected lesion
- Type of specimen:
 - Excision without wire localization
 - Excision with wire localization; for these specimens, the specimen radiograph with an interpretation should be made available to the pathologist
 - Nipple duct excision
 - Total mastectomy
 - Lymph node specimen (sentinel node, nonsentinel node, limited axillary dissection, complete axillary dissection)
